**Keywords:** composite indicators, development, dimensional weights

**Abstract**

Measuring countries' levels of development is one of the most complex tasks in economics. The recognized multidimensionality of the phenomenon has increasingly led to the use of composite indicators in order to overcome the limitations usually identified in such measures as the income per capita (Bandura, 2008 [1]; Saisana, 2008 [2]). Using indicators such as this to assess development raises two crucial issues. On the one hand, one needs to identify the dimensions of development for each indicator as well as the content of each dimension. On the other hand, one also needs to assign weights to each dimension in order to have an aggregated indicator.

This second issue has drawn little attention in the literature, and usually equal weights are attributed to all the dimensions of a given indicator. In the absence of any systematic analysis of their correspondence to the public perception regarding the importance of each dimension of development, these weights are arbitrarily fixed. This is so despite the fact that individuals are the ultimate beneficiaries of countries' development. The present paper seeks to close this gap in the literature, discussing in an explicit manner, the importance of the weights of each dimension of development.

# New Challenges of Economic and Business Development – 2012

May 10 - 12, 2012, Riga, University of Latvia

Using a public-opinion survey conducted in Portugal, we evaluate the importance of the main dimensions of development and examine if the dimensional weights depend on individual characteristics of the respondents, such as gender, age, or educational level. The evidence suggests that both education and health regularly stand out as the most highly-rated factors.

## 1. Introduction

Measuring and quantifying development makes increasing use of composite indicators. This raises the issue of the determination of the proper weighting of the various dimensions considered. The present paper aims to answer three research questions based on responses to a survey conducted in Portugal. First, do the results of the survey sustain the predominant adoption in the literature of equal weights for several issues affecting a country's development? Second, does the importance of the different dimensions of development vary according to individual characteristics of the respondents, such as gender, age, or educational level? Third, does any relationship emerge between the different dimensional weights?

The paper is structured in six sections. Section 2 discusses the progressive enlargement of the concept of development as well as the importance of its composite measurement approach. Section 3 proposes a development nomenclature and discusses the issue of the weights by evaluating the importance that the Portuguese public opinion attributes to each dimension. Section 4 compares the results identified in section 3 with what has been most frequently adopted in a broad set of available composite indicators. Section 5 evaluates the relevance of some conditioning factors to the weights obtained in section 3. Section 6 investigates the relationships between the different dimensions of development. Section 7 presents some final remarks.

## 2. The Relevance of the Composite Measurement of Development

Development is undoubtedly one of the most discussed concepts in economics. For many years, and especially since the end of the Second World War, development of countries has been evaluated almost exclusively in terms of their level of economic growth. Economic growth has been seen as a necessary and sufficient condition to development and, therefore, improvement in the well-being of the population has been viewed as relying on it. Regarding the quantitative assessment of a country's level of development, the more immediate implication of this strict link between the two concepts is the heavy reliance on indicators of economic activity, notably the level of income per capita.

However, since the 1970s a decisive turning point in the practices and approaches to development has led to the emergence of new and broader concepts of development. These new concepts are couched mainly in an interdisciplinary and multidimensional perspective, spawning the current concepts of sustainable, local, participative, human, and social development.

In the same vein, several attempts have been advanced to amend, complement, or replace the income per capita as a summary measure of development, and in turn, the approach to measuring development has progressively evolved from a uni- to a multi-dimensional character. Composite indicators of development have gained great importance as a result, and many have

# New Challenges of Economic and Business Development – 2012

May 10 - 12, 2012, Riga, University of Latvia

appeared in recent years, allowing for a more textured assessment of the phenomenon of development (Booyesen, 2002 [3]; Bandura, 2008 [1]; Saisana, 2008 [2]).

Composite indicators are mathematical combinations of a set of indicators. Their extensive use has led to a spirited debate over the conceptual and methodological arguments in favor of and against this measurement approach. In a detailed analysis of the relevance of these types of indicators, Booyesen (2002) [3] stresses some of their most important limitations: (i) composite indicators always exclude one or more essential elements of the domain at issue; (ii) particular components of the index may be quantified with the aid of different variables (possibly better ones); (iii) composite indicators may be unable to reveal more than what a single variable alone reveals; (iv) the selection process of the variables may be *ad hoc*, which is to say, politically or ideologically motivated, or simply determined by the availability and accuracy of data; (v) the data employed in composite indicators are often inaccurate and non-comparable; (vi) often no clear rationale is presented for the selected weighting and aggregation techniques; (vii) composite indicators may lack practical value if they give no specific and focused policy advice.

However, many elements in favor of composite indicators exist as well, mainly the following (Saisana and Tarantola, 2002 [4]): (i) composite indicators synthesize complex or multidimensional issues; (ii) they are easier to interpret than a battery of separate indicators; (iii) they facilitate the task of comparing the performance across countries and their progress over time, and thereby attract public interest; (iv) they reduce the size of a list of indicators without losing basic information. The main advantage of composite indicators is, indeed, their multidimensionality, since they represent aggregate and relatively simple measures of a combination of components of complex phenomena (Booyesen, 2002 [3]).

Currently, a considerable variety of composite indicators have been proposed to quantitatively assess the performance of countries in terms of development.<sup>1</sup> These development indicators are employed with the aim of measuring the main constituents of the phenomenon, thereby reflecting its multidimensional nature. Many proposals of disaggregation of the phenomenon into its main dimensions exist in the literature.<sup>2</sup>

### 3. The Importance of Dimensional Weights – Findings from Portugal

Based on the criteria of intrinsic relevance and recurring inclusion in alternative attempts of development disaggregation, we propose a nomenclature that disaggregates development into eight dimensions encompassing crucial features that determine the level of countries' development: (i) income; (ii) income distribution (inequality and poverty); (iii) education; (iv) health; (v) employment (in quantitative as well as qualitative terms); (vi) infrastructure; (vii) values (economic freedom, socio-political liberty, including the political regime, corruption, and respect for human rights); (viii) environment.

We have conducted a small survey in order to measure the importance of each of the above dimensions. The questionnaire contained a brief description of the key elements of each

<sup>1</sup> Even though some proposed indicators might not have the direct purpose of measuring development, they are likely to be interpreted as such.

<sup>2</sup> See, for instance, Booyesen (2002) [3].

## New Challenges of Economic and Business Development – 2012

May 10 - 12, 2012, Riga, University of Latvia

dimension, and individuals were asked to indicate their opinion of the relative importance of each dimension to the development of a given country. Additionally, certain characteristics of the respondents were collected (gender, age, and level of education). The survey was conducted between April and July of 2010 and included a total sample of 2892 observations.

Table 1 presents the overall findings, highlighting for each dimension the average, the standard deviation, the maximum value, the number of responses with zero weight to that dimension, the distance from the average (which is 12.5%), and the number of observations above the average. We have designated the best situation in bold and the worst situation in italics.<sup>3</sup>

Table 1

### Dimensional weights – global results

Dimension	Average	Standard deviation	Max.	No. of zeros	Distance from average	% of obs. above average
Income	<i>12.11%</i>	1.47	40.82%	4	<i>-0.39 p.p.</i>	36.65%
Income Distrib.	12.14%	1.57	<b>68.97%</b>	<i>15</i>	-0.36 p.p.	43.05%
Education	<b>13.35%</b>	1.16	46.15%	2	<b>0.85 p.p.</b>	<b>72.10%</b>
Health	13.06%	1.06	35.00%	<b>1</b>	0.56 p.p.	65.21%
Employment	12.61%	1.13	30.43%	<b>1</b>	0.11 p.p.	52.84%
Infrastructure	12.16%	1.24	36.59%	2	-0.34 p.p.	<i>36.62%</i>
Values	12.32%	1.40	30.61%	6	-0.18 p.p.	44.40%
Environment	12.26%	1.26	<i>29.94%</i>	4	-0.24 p.p.	43.71%

As Table 1 reveals, the difference between the weights assigned to the different dimensions is not very great, thereby supporting the option frequently adopted in the literature of applying equal dimensional weights to all included dimensions. However, a more in-depth analysis of the survey's findings points to some additional messages of interest. We emphasize three of them.

First of all, two dimensions – education and health – are identified as being more relevant than the others. If we use the number of responses above the average (12.5%) as the analysis criterion, this finding is very clear. Indeed, with regard to education, 72.10% of the respondents assigned a weight above the average. The value for the health dimension is 65.21%, and employment is the other dimension to which more than half of the respondents attributed an importance greater than the average (52.84%). On the other hand, only 36.62% of the respondents evaluated infrastructure as greater than the average.

Second, the results for income distribution (inequality and poverty) should also be pointed out. That dimension presents the greatest disparity of responses as evidenced by the largest standard deviation, the largest number of responses that assigned a zero weight to that dimension, and finally, by including the response that attributed the greatest weight to any dimension (68.97%).

Third, the income dimension has – somewhat surprisingly – a low weight, which seems to support the notion that evaluating development focused exclusively on that dimension is clearly

<sup>3</sup> We adopt this procedure in all of the tables presented in this study.

reductive and does not correspond to the perception that public opinion has about the fundamental components of the process of development.

#### 4. The Dimensional Weights in the Measurement of Development

Let us now compare the findings above to those reported in the literature. The first of the three research questions posed in the Introduction can be further subdivided into two parts:

(i) Do the most valued dimensions (revealed in our survey) correspond to those most frequently included in composite indicators of development?

(ii) Do the weights found correspond to those applied in the main composite indicators of development (as reported in the literature)?

This section seeks to answer these two questions. To achieve this, we follow a four-step procedure. First, we identify surveys and other recent studies that include a list of composite indicators of development. Second, we establish a selection criterion for the indicators included in those studies. In particular, we consider the indicators that simultaneously include at least two of the different proposed dimensions and are mentioned in at least two of the selected studies.<sup>4</sup> Third, the selected indicators are analyzed in order to identify the dimensions included in each indicator. Fourth, we evaluate the weights adopted in each case.

The studies selected for the first step are the following: (i) Booyen (2002) [3]; (ii) Morse (2004) [5]; (iii) Gadrey and Jany-Catrice (2007) [6]; (iv) Goossens *et al.* (2007) [7]; (v) Afsa *et al.* (2008) [8]; (vi) Bandura (2008) [1]; (vii) Eurostat (2008) [9]; (viii) Saisana (2008) [2]; (ix) Soares and Quintella (2008) [10]; (x) Singh *et al.* (2009) [11]. Applying the selection criterion presented in the second step led to the choice of 54 composite indicators of development. In the third step we identified the dimensions of development included in each of the 54 indices selected, in order to address the first question presented above. Table 2 summarizes the results of this procedure.

Table 2

#### No and % of composite indicators taking into account each dimension of development

Dimension	No and %
Income	24 (44.4%)
Income Distribution	14 (25.9%)
Education	<b>37 (68.5%)</b>
Health	35 (64.8%)
Employment	22 (40.7%)
Infrastructure	27 (50.0%)
Values	26 (48.1%)
Environment	19 (35.2%)

As Table 2 reveals, the two dimensions most often included in composite indicators of development are also those that seem most valuable in the public opinion according to the

<sup>4</sup> The purpose of the mentioned criterion is to identify the most representative indicators and thereafter discard the least consolidated contributions in the literature.

findings of our survey – education and health. The greatest discrepancies between the findings of the survey and the inclusion of dimensions in indices of development are seen in the infrastructure and income dimensions. Both are deemed to be less valuable in the public opinion than the frequency with which they are considered in the 54 indices of development would lead one to believe. The opposite is observed with the employment and environment dimensions, which our survey finds to be more valuable in the public opinion.

We turn now to the second part of the question. Upon analyzing the weighting methods employed in the 54 composite indicators of development, four alternative methodologies stand out.

The first option (EW) is to employ equal weighting (i.e., not to use differentiated weights, at all). In this option, the composite indicator is determined by the simple average of the corresponding indicators, which, in turn, might be simple or composite in nature.

Where dimensional weights are employed in a differentiated manner, the literature offers a variety of weighting methods, usually segregated into two broad categories – statistical methods (option two) and participatory methods (option three) (OECD and European Commission, 2008)[12]. In option two, statistical techniques of multivariate analysis, such as the principal component analysis or the factor analysis, are of particular interest. Both methods group individual indicators according to their correlation degree. Option three (participatory methods) are based on expert or public opinion, and methodologies known as budget allocation (BA) or public opinion (PO) are well-known examples.

The fourth option is to employ unequal weightings based on an *ad-hoc*/subjective process that is based on authors' (experts') opinion and/or intuitive appeal.

Table 3 summarizes the methodology used in each of the 54 composite indicators of development considered in the present section.

<b>Total (number of indices per method)</b>		<b>40</b>	<b>6</b>	<b>7</b>	<b>2</b>	<b>1</b>	<b>15</b>

<sup>1</sup> In the case of revised indices, the last revision available (at table construction date) was used. In the case of indices periodically published, the last version available (at table construction date) was used. For some indices, the only information available is on the website, namely, the following: (i) GNH index – <http://www.grossnationalhappiness.com/>; (ii) ISEW – <http://www.foe.co.uk/community/tools/isew/>; (iii) BIP40 – <http://www.bip40.org/>

<sup>2</sup> The list encompasses indices that capture, at least, two dimensions of the development nomenclature – and are, thus, multidimensional indices of development – and, in addition, are mentioned in, at least, two of the selected studies. Development nomenclature: (i) income; (ii) income distribution; (iii) education; (iv) health; (v) employment; (vi) infrastructure; (vii) values; (viii) environment. Selected studies: (i) Booyesen (2002); (ii) Morse (2004); (iii) Gadrey and Jany-Catrice (2007); (iv) Goossens et al. (2007); (v) Afssa et al. (2008); (vi) Bandura (2008); (vii) Eurostat (2008); (viii) Saisana (2008); (ix) Soares and Quintella (2008); (x) Singh et al. (2009).

<sup>3</sup> EW = Equal Weighting; PCA/FA = Principal Components Analysis or Factor Analysis; Others = Mainly procedures where components scores are weighted by their coefficients of correlation or regression; BA = Budget Allocation; PO = Public Opinion.

As can be seen in Table 3, the weighting method that is based on public opinion is rarely used – being present in only one of the 54 indices. The simplest method – EW – is the one most favored – being used in 40 of the 54.<sup>5</sup> Note that the common procedure reported in the literature is not necessarily the option of no weighting, but rather that weights are, implicitly, equal.

In the most popular indicator for measuring development in a composite nature – the Human Development Index (HDI) – a weighting of 1/3 is attributed to each of its constituents –

<sup>5</sup> The assignment of equal weights to all the dimensions might be followed by the option of unequal weighting for the possible sub-dimensions of each included dimension.

income, education and health. This stands in contrast to the findings of our survey, in which public opinion seems to place greater value on education and health, while de-emphasizing income.

## 5. Conditioning Factors of the Weights

Section 3 presented the overall findings of the survey conducted on dimensional weighting. The purpose of the present section is to evaluate whether or not these weights differ according to selected characteristics of the respondents: gender, age, and educational level. We start by comparing the dimensional weights assigned by men (1403 observations) and women (1480 observations). Table 4 presents the results.<sup>6</sup>

Table 4

**Dimensional weights by gender**

Dimension	Men			Women		
	Average	Distance from average	% of obs. above average	Average	Distance from average	% of obs. above average
Income	12.14%	-0.36 p.p.	37.63%	12.06%	-0.44 p.p.	35.54%
Income Distrib.	12.04%	-0.46 p.p.	41.12%	12.24%	-0.26 p.p.	43.92%
Education	<b>13.46%</b>	<b>0.96 p.p.</b>	<b>75.91%</b>	<b>13.23%</b>	<b>0.73 p.p.</b>	<b>68.38%</b>
Health	13.06%	0.56 p.p.	65.36%	13.06%	0.56 p.p.	65.07%
Employment	12.48%	-0.02 p.p.	48.97%	12.73%	0.23 p.p.	56.42%
Infrastructure	12.12%	-0.38 p.p.	37.56%	12.19%	-0.31 p.p.	35.61%
Values	12.44%	-0.06 p.p.	48.40%	12.22%	-0.28 p.p.	40.68%
Environment	12.26%	-0.24 p.p.	46.26%	12.27%	-0.23 p.p.	41.28%

The evidence in Table 4 confirms the importance given to both education and health by both women and men. 75.91% of men and 68.38% of women assigned a weight to education greater than the average. In comparative terms, we should mainly highlight the greater valuation that men attributed to both education and values (compared to women) and that women attributed to both employment and income distribution (compared to men), while the remaining dimensions show very similar values. The results also reveal the lower importance that women give to income, and men give to income distribution as components of a country's development.

We now examine the division of the sample according to age, considering four age groups: (i) up to and including 25 years of age; (ii) 26 to 39; (iii) 40 to 54; (iv) 55 and over. The data are in Table 5.<sup>7</sup>

<sup>6</sup> Nine respondents did not identify their gender and thus were excluded from the analysis.

<sup>7</sup> 292 respondents did not identify their age.

Table 5

## Dimensional weights by age

Dimension	Up to 25			26-39		
	Average	Distance from average	% of obs. above average	Average	Distance from average	% of obs. above average
Income	12.53	0.03 p.p.	46.20%	12.04	-0.46 p.p.	35.44%
Income Distrib.	12.33	-0.17 p.p.	50.63%	12.10	-0.40 p.p.	43.12%
Education	<b>13.20</b>	<b>0.70 p.p.</b>	<b>68.78%</b>	<b>13.36</b>	<b>0.86 p.p.</b>	<b>72.88%</b>
Health	13.06	0.56 p.p.	68.35%	13.07	0.57 p.p.	66.40%

Employment	12.43	-0.07 p.p.	45.99%	12.60	0.10 p.p.	56.66%
Infrastructure	12.21	-0.29 p.p.	35.46%	12.25	-0.25 p.p.	38.57%
Values	12.41	-0.09 p.p.	45.10%	12.49	-0.01 p.p.	44.03%
Environment	12.36	-0.14 p.p.	42.73%	12.34	-0.16 p.p.	47.78%

As seen in Table 5, education is always regarded as the most important component in the process of a country's development, no matter what age group is responding, even though the importance attributed increases with the age of the respondent. The relative weights of both values and infrastructure go in the same direction. Inversely, the greater the age, the lower is the weight attributed to income. If we compute the correlation coefficient between the age of the respondents and the weights they assigned to each dimension of development, we obtain a negative association for income, income distribution, and employment. The relative importance of these dimensions is thus greater for the younger population. A positive correlation is present for the remaining dimensions.

Finally, we disaggregate the sample according to the schooling level. For this we consider four categories: (i) up to and including 9 years of education; (ii) 10 to 12 years; (iii) with an undergraduate degree; (iv) with a post-graduate degree, i.e., Masters, or Doctoral Degree. The data are in Table 6.<sup>8</sup>

<sup>8</sup> Eleven respondents did not identify their educational level.

Table 6

## Dimensional weights by educational level

Dimension	Up to 9 years			10-12 years		
	Average	Distance from average	% of obs. above average	Average	Distance from average	% of obs. above average
Income	11.87	-0.63 p.p.	41.46%	12.34	-0.16 p.p.	40.57%
Income Dist.	<i>11.64</i>	<i>-0.86 p.p.</i>	40.00%	12.27	-0.23 p.p.	43.41%
Education	<b>13.71</b>	<b>1.21 p.p.</b>	<b>69.27%</b>	<b>13.16</b>	<b>0.66 p.p.</b>	<b>65.11%</b>
Health	13.64	1.14 p.p.	66.83%	13.09	0.59 p.p.	64.27%
Employment	12.59	0.09 p.p.	58.54%	12.70	0.20 p.p.	54.76%
Infrastructure	12.26	-0.24 p.p.	43.90%	12.08	-0.42 p.p.	<i>34.39%</i>
Values	12.21	-0.29 p.p.	<i>39.02%</i>	<i>12.02</i>	<i>-0.48 p.p.</i>	<i>34.39%</i>
Environment	12.08	-0.42 p.p.	45.85%	12.34	-0.16 p.p.	45.58%

Dimension	Undergraduate degree			Masters, or Doctoral degree		
	Average	Distance from average	% of obs. above average	Average	Distance from average	% of obs. above average
Income	12.22	-0.28 p.p.	<i>37.04%</i>	<i>11.89</i>	<i>-0.61 p.p.</i>	<i>32.64%</i>
Income Dist.	<i>12.09</i>	<i>-0.41 p.p.</i>	41.52%	12.27	-0.23 p.p.	45.43%
Education	<b>13.22</b>	<b>0.72 p.p.</b>	<b>69.51%</b>	<b>13.52</b>	<b>1.02 p.p.</b>	<b>80.04%</b>
Health	12.93	0.43 p.p.	63.95%	13.02	0.52 p.p.	66.94%
Employment	12.65	0.15 p.p.	53.99%	12.49	-0.01 p.p.	48.86%
Infrastructure	12.23	-0.27 p.p.	37.40%	12.10	-0.40 p.p.	35.34%
Values	12.33	-0.17 p.p.	45.02%	12.52	0.02 p.p.	51.14%
Environment	12.33	-0.17 p.p.	44.04%	12.18	-0.32 p.p.	41.58%

Table 6 reveals some interesting results. Respondents with intermediate levels of schooling (the categories of “10 to 12 years of schooling” and “with an undergraduate degree”) attributed greater importance to income. The same is found for both employment and environment, even though the difference between these two groups of schooling level and the remaining two is now less significant. As expected, the highest educational level group gave a very high weight to education, with 80.04% of the respondents in this group assigning a relative weight greater than the average.<sup>9</sup> There is also a strong depreciation of the income dimension in this group.

<sup>9</sup> A conventional practice of selecting weights in a participatory manner is by following the consultation of experts. Given that the higher educational level group proxies experts, a closer inspection of the perception it has on the fundamental components of the process of development would be valuable and very welcome.

## 6. Is There a Relationship between Weights?

In the sections above we analyzed how the respondents evaluated each of the different dimensions of development. In this section we investigate what type of relationship exists between the several dimensional weights. For instance, considering the findings of our survey, does a higher valuation for infrastructure correspond to a lower valuation for environment, or does a higher valuation of health correspond to a lower valuation of income?

Table 7

Correlation coefficients between dimensional weights

	Income	Income Dist.	Educ.	Health	Employ.	Infrast.	Values	Environ.
Income	-	-0.060	-0.155	-0.238	-0.119	-0.066	-0.215	-0.361
Income Dist.	-0.060	-	-0.210	-0.264	-0.240	-0.301	-0.149	-0.212
Education	-0.155	-0.210	-	<b>0.163</b>	-0.047	-0.173	-0.218	-0.184
Health	-0.238	-0.264	<b>0.163</b>	-	0.087	-0.110	-0.264	-0.061
Employment	-0.119	-0.240	-0.047	0.087	-	-0.146	-0.230	-0.078
Infrastructure	-0.066	-0.301	-0.173	-0.110	-0.146	-	-0.038	-0.026
Values	-0.215	-0.149	-0.218	-0.264	-0.230	-0.038	-	0.063
Environment	-0.361	-0.212	-0.184	-0.061	-0.078	-0.026	0.063	-

Table 7 refers to the weights assigned by individuals to each dimension. Therefore, a negative correlation coefficient is expected in the majority of the bilateral comparisons. The evidence supports this in 25 out of the 28 possible relationships. Two of the three exceptions correspond to the relationship among key social dimensions of development – education, health, and employment – and the most significant association is between education and health (0.163). The other bilateral relationship with a positive association of attributed weights has to do with the relationship between values and environment. Here we find that individuals who give greater importance to the values dimension also seem to have a greater environmental concern. The trade-off between environment and income is clearly evidenced by the corresponding bilateral relationship, which has the largest negative correlation coefficient.

## 7. Final Remarks

Composite indicators in the assessment of countries' development have gained increasing importance *vis-à-vis* the enlargement of the concept and the subsequent need for indicators to capture that multidimensional nature in the quantitative evaluation of the domain. The crucial issues regarding composite indicators are the dimensions encompassed by each, and their respective weights. The second issue is less clarified in the literature and is thus at the center of this investigation.

The Introduction posed three key research questions, and based upon the findings, our main conclusions can now be stated. The first question was about the correspondence between the

## New Challenges of Economic and Business Development – 2012

May 10 - 12, 2012, Riga, University of Latvia

public-opinion valuations of each dimension of development and the common procedure in the literature of assigning equal weight to each of these dimensions. Two major conclusions can be derived from our findings. On the one hand, respondents have assigned very similar weights to the different dimensions, which seems to add legitimacy to the research option that predominates in the literature. On the other hand, some key dimensions of development are repeatedly identified as being more important than others – namely education and health. Both infrastructure and income are, in contrast, the dimensions that are least frequently identified as having an importance greater than the other dimensions of development. In short, even though the differences are not quantitatively significant, they are consistent in terms of the more important dimensions, thereby reducing the value of composite indicators that do not include them. However, the analysis of the main available indices in the literature confirms that these dimensions are, indeed, those that are most frequently included in the composite measurement of development.

The second question presented in the Introduction has to do with the dependence of dimensional weights on some characteristics of the individuals – namely gender, age, and educational level. The evidence confirms the influence of these characteristics, although the impact is, once again, not great.

Finally, regarding the third research question, about the possible existence of a relationship between dimensional weights, the data support a belief in such a relationship. The greatest positive relationship is between education and health. Respondents who assign more weight to the education dimension do the same for the health dimension. Other positive correlations are found between employment and health and between environment and values. The remaining bilateral relationships have a negative correlation, which comes as no surprise considering that relative weights are at the focus. The most significant inverse relationship is between income and environment.

There is still room for further research on the issue of weighting composite indicators of development. We emphasize those that seem most promising in the area. First of all, a larger survey would allow for a more robust look at the findings reported here. Second, broadening the elements of individual characterization of the respondents would enable a more in-depth evaluation of the factors determining the dimensional weights of development. Third, a comparison of our findings with those obtained in different countries would be very beneficial. Indeed, one cannot expect that findings from Portugal generalize to all countries of the world economy and thus it would be really interesting to look at the issue of weighting composite indicators of development especially in comparisons between developed and developing countries, but also taking into account sub-groups of countries like the least-developed countries and the emerging economies. Fourth, dimensional surveys questioning the relative importance of each sub-dimension is a highly appealing avenue for further research. This procedure would have a double merit. First, it would enrich the corpus of information available, and second, it would allow for a more specific analysis, and thus a more insightful classification by respondents. In addition, dimensional surveys could also be used as a further check on the proposed development nomenclature, namely whether aspects of development such as gender equality, cultural diversity, macroeconomic context, and political and social stability do have a residual character for individuals. Finally, a long-run study would permit monitoring the (possibly changing) attributions that individuals provide on the dimensions of development throughout their lives.
